

Lesson 7

Security Considerations

Objectives

- Audit
- Encryption
- Data Vault
- Some fine-control capabilities

2

Traditional audit

3

- None of the parameters are PDB modifiable
- Purge the audit trail in each container
- Audits configured in the root apply to all containers
- Audits configured in a PDB have local scope
 - Records visible in the local audit trail
 - Also in CDB_AUDIT_TRAIL in the root
- Defaults for CONTAINER = current | all

Traditional audit:

In a PDB, AUDIT DROP ANY TABLE BY SYSTEM BY ACCESS CONTAINER = CURRENT;

In the root, AUDIT DROP ANY TABLE BY SYSTEM BY ACCESS CONTAINER = ALL;

For audits that specify objects or users, if executed in the root they must be common objects or users.

Unified audit

4

- Each container has its own unified audit trail
- Purge within each container
- Create local policies in each container
- Use the CONTAINER clause in the root container
 - CURRENT means the root container only
 - ALL will propagate the policy to all containers
- CDB_UNIFIED_AUDIT_TRAIL consolidates the records
- Fine Grained Audit is always within a PDB

A common unified audit policy:

```
CREATE AUDIT POLICY any_trigger PRIVILEGES CREATE ANY TRIGGER  
CONTAINER=ALL;
```

Enabling a common policy (which does not take a CONTAINER clause) enables it in all PDBs. Within each container, the UNIFIED_AUDIT_TRAIL view shows audited events in that container. In the root, the CDB view shows everything.

Fine Grained Audit can be configured only in containers, not as common policies. This applies whether Unified Audit has been enabled or not.

Transparent Data Encryption: United Mode

5

- There is one keystore for the CDB
 - Administered from the root
 - Opened or closed for each PDB
 - Location specified in sqlnet.ora file or parameters
- Keys are managed within each PDB
 - A master key for each PDB
 - V\$ENCRYPTION_KEYS shows detail
- Keys for a PDB can exported and imported
 - Permits relocating a PDB that has TDE objects
 - Automate: ONE_STEP_PLUGIN_FOR_PDB_WITH_TDE

"United Mode" is the term introduced in release 18 to describe PDBs using TDE in the release 12 fashion.

There is one keystore per database. Within a CDB, the keystore has a set of keys per container. The keystore is created from the root, then within each PDB the keystore can be opened and closed.

The location and type of the keystore is specified either with the sqlnet.ora parameter `SQLNET.ENCRYPTION_WALLET_LOCATION` as in earlier releases, or with the `WALLET_ROOT` and `TDE_CONFIGURATION` instance parameters.

To move a PDB with TDE enabled from one CDB to another, it is necessary to export the keys from the source CDB's keystore and import them into the destination CDB's keystore. When doing this, it is necessary to provide the keystore password. Setting `ONE_STEP_PLUGIN_FOR_PDB_WITH_TDE=true` permits automating this process when doing a remote network clone.

Keystore parameters

6

- WALLET_ROOT
 - Not PDB modifiable
 - A directory beneath which many wallets are created
 - Subdirectories per PDB
 - Sub-subdirectories per wallet type
- TDE_CONFIGURATION
 - PDB modifiable, to enable Isolated Mode
 - Specifies the type of keystore
 - Use double quotes, not single quotes

The wallet_root determines the location of the wallet(s) and is set in the root container. For example,

```
wallet_root=/app/oracle/admin/orcl/wallet
```

Then set tde_configuration to the type of wallet. For example.

```
tde_configuration="keystore_configuration=file"
```

The examples above would be equivalent to this entry in sqlnet.ora:

```
encryption_wallet_location=  
(source=(method=file)(method_data=(directory=/app/oracle/admin/orcl/wallet)))
```

The possibilities for the keystore_configuration are

FILE: a wallet based keystore

OKV: an Oracle Key Vault keystore

HSM: an externally provided Hardware Security Module

If tde_configuration is set only in the root container, then TDE will be running in United Mode. Setting it in a PDB converts that PDB to Isolated Mode.

v\$encryption_wallet shows the mode of each container.

Transparent Data Encryption: Isolated Mode

7

- Available on all Engineered Systems
 - On-premises ODA or Exadata
 - DBCS (Oracle Database Cloud Service) various options
 - Latest RUs: available on all platforms
- Each PDB manages its own keystore
- Enable by setting tde_configuration in a PDB
- Makes some operations easier
 - PDB relocation from one CDB to another
 - Plugging and unplugging PDBs

Isolated mode is aimed at easing management of large scale environments. In cases where there is a fleet of CDBs supporting hundreds or thousands of PDBs there will be frequent requirements to move PDBs around. This might be for upgrade and patching, or perhaps to balance workloads across CDBs and servers. In such cases, the process of exporting and importing keys from the United Mode wallets complicates the processes hugely and may make automation impossible.

Data Vault

8

- The Data Vault option must be installed in the CDB
 - Use for new PDBs or when plugging in
 - CHECK_PLUG_COMPATIBILITY will detect problems
- Each PDB has its own Data Vault metadata
 - Realms, rule sets, command rules, default policies
 - The DVSYS and DVF schemas are common
- Enable Data Vault in the root
 - STRICT mode forces use in all PDBs
 - REGULAR mode lets some PDBs function normally

Data Vault can control privileged user access within PDBs for both local and common users. Individual local policies can be created for each PDB. When Data Vault protects an object, Data Vault subjects common privileges for common objects to the same enforcement rules as local system privileges.

In the strict mode, settings propagate from the root to all containers. In this mode, and PDBs where Data Vault is disabled will operate in restricted mode only. In regular mode, PDBs where Data Vault is not enabled function as normal.

Enabling non-CDB compatibility

9

- Some actions are impossible in a PDB
 - Controlfile backup
 - Managing the redo log
- Legacy code may fail in a PDB
- To permit non-CDB like behaviour:
 - Noncdb_compatible = true | false
- Consider the implications for security

Many ALTER SYSTEM and ALTER DATABASE commands will fail if executed in a PDB. In some cases, the failure is silent and in others an error will be returned. These statements can be permitted to succeed by setting noncdb_compatible=true. The security implications of this may be considerable, in that the DBA of one container can now perform tasks that will impact on the entire CDB.

Operating system credentials

10

- By default, OS interactions use the Oracle owner
 - External jobs
 - External procedures
- Recommendation is to create an OS user per PDB
- Create the OS credentials in the root container
- Nominate a credential in each PDB

Unless configured otherwise, any access to the server's operating system is accomplished in the security context of the Oracle owner. Oracle's advice is:

For better security, Oracle recommends that you set a unique operating system user for each PDB in a multitenant environment. Doing so helps to ensure that operating system interactions are performed as a less powerful user than the oracle operating system user, and helps to protect data that belongs to one PDB from being accessed by users who are connected to other PDBs.

To set up this environment:

Create an OS user for each PDB, with appropriate OS permissions

In the root container,

```
Exec dbms_credential.create_credential ('pdba_cred', '<username>', '<password>')
```

In the pluggable container,

```
Alter system set pdb_os_credential=pdba_cred scope=spfile;
```

Note that running jobs as the Oracle owner is bad practice in any database, and that OS credentials should always be supplied irrespective of whether the database is CDB or non-CDB.

Lockdown profiles

11

- Restricts operations possible in a PDB
 - Features, such as network access or security facilities
 - Options, such as partitioning
 - Statements, such as ALTER SYSTEM

- Configure in the root, enable in the PDB

```
create lockdown profile ... ;  
alter lockdown profile ld1 [ disable | enable ]  
    [ feature | option | statement ] ... ;  
alter session set container=... ;  
alter system set pdb_lockdown = ... ;
```

- Examples

```
feature = ('network_access', 'os_access', utl_tcp')  
option = ('partitioning')  
statement = ('alter system') (clause = 'set')
```

The lockdown profile capability is clearly aimed at cloud service providers. It gives the ability to control what the users of a any one container can do. So even though, for example, partitioning might be licensed it will be usable in only some containers.

Security: summary

12

- Audit can be configured at CDB and PDB levels
 - Traditional audit is always configured in the PDBs
 - Unified Audit permits central control from the root
- Transparent Data Encryption
 - Unified Mode: one wallet per CDB
 - Isolated Mode: one wallet per PDB
- Data Vault is also Multitenant aware

Exercise

- Use Unified Audit
- Configure TDE in United Mode
